**Abstract**—Frequency selective surfaces (FSSs) with fractal four legged aperture elements are studied. Three different order fractal elements are discussed for comparison. The results show that by using this novel kind of elements, multiband FSSs with miniaturized elements can be achieved. The ratio of the first resonant wavelength to the periodicity can be up to 10.36. Four passbands for normal incidence or two stable passbands for different incident angle and polarizations can be obtained. The FSS is analyzed by the spectral domain approach.

### **1. INTRODUCTION**

Frequency selective surfaces, which are used widely as microwave absorbers [1] and filters [2], have been extensively investigated over the years [3–8]. In many communication situations, multiband FSSs are required. Several techniques for multiband FSSs have been presented in the previous papers: layered FSS [3], perturbation of a single-layered FSS [4], and the use of multiresonant elements such as Sierpinski dipole elements [5], double square loop elements [3] and fractal cross dipole elements [14]. In practice, The FSS with multiresonant elements has the advantages of a lighter structure, a simplified design and ease to fabricate.

In the conical radome applications, curved FSSs with large curvature are required. In this context, FSSs with miniaturized elements are preferred, since small unit cells are distorted less and in turn less distortion of the transmission response. In the metamaterial applications, such as artificial magnetic conductor, miniaturized element is also required to facilitate flexible spatial filtering for an arbitrary wavefront. In [9], the fractal Hilbert curves are used to reduce the element size. In [10], the improved Gangbuster elements are used.

In this paper, FSSs with fractal dipole aperture elements are presented. Three different order fractal elements are discussed. The results show that both multiband and miniaturized elements can be effected by using higher order fractal elements.

## 2. FRACTALS AND THEIR APPLICATIONS

Fractals are geometrical shapes that are self similar, and can generate almost any complex structure in nature, through iterating of certain simple geometries. By using fractal shapes, an arbitrarily long curve confined in a given volume can be obtained. This property has been shown effective in reducing the spacing between resonant elements in an FSS [9] and in reducing the volume occupied by small antennas [11]. And by exploiting the self-similarity property of fractals, multiband and wideband behaviors can be achieved in both FSS [6, 14] and antenna [12, 13] applications.

## 3. ANALYSIS OF FSSS USING SPECTRAL DOMAIN APPROACH

Spectral domain approach has been successful in analyzing frequency selective surfaces [2]. First, the Green's function of the multilayered media is calculated in the spectral domain, by using the transmission line theory. Then, the electric field integral equation (EFIE) at the conducting sheet can be written as

$$\begin{cases} E_x^{inc}(x, y) = \frac{1}{(2\pi)^2} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (\tilde{G}_{xx}\tilde{J}_x + \tilde{G}_{xy}\tilde{J}_y) e^{j(\alpha x + \beta y)} d\alpha d\beta \\ E_y^{inc}(x, y) = \frac{1}{(2\pi)^2} \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (\tilde{G}_{yx}\tilde{J}_x + \tilde{G}_{yy}\tilde{J}_y) e^{j(\alpha x + \beta y)} d\alpha d\beta \end{cases} \quad (1)$$

where  $E_x^{inc}(x, y)$ ,  $E_y^{inc}(x, y)$  are the incident field when the conducting sheet does not exist,  $\tilde{G}_{xx}$ ,  $\tilde{G}_{xy}$ ,  $\tilde{G}_{yx}$ ,  $\tilde{G}_{yy}$  are components of the dyadic Green's function, and  $\tilde{J}_x$ ,  $\tilde{J}_y$  are the electric current induced on the sheets. It is noted that the script ' $\tilde{\cdot}$ ' means the Fourier transformation, which is defined as

$$\tilde{F}(\alpha, \beta) = \iint_{-\infty}^{+\infty} F(x, y) e^{-j(\alpha x + \beta y)} dx dy \quad (2)$$

Because the FSS is periodical, the integration becomes doubly infinite summations of Floquet harmonics, that is

$$\begin{cases} E_x^{inc}(x, y) = \frac{1}{T_x T_y} \sum_{p=-\infty}^{+\infty} \sum_{q=-\infty}^{+\infty} \left( \tilde{G}_{xx} \tilde{J}_x + \tilde{G}_{xy} \tilde{J}_y \right) e^{j(\alpha_p x + \beta_q y)} \\ E_y^{inc}(x, y) = \frac{1}{T_x T_y} \sum_{p=-\infty}^{+\infty} \sum_{q=-\infty}^{+\infty} \left( \tilde{G}_{yx} \tilde{J}_x + \tilde{G}_{yy} \tilde{J}_y \right) e^{j(\alpha_p x + \beta_q y)} \end{cases} \quad (3)$$

where  $T_x$ ,  $T_y$  are periodicities, and  $\alpha_p$ ,  $\beta_q$  are known as Floquet harmonics, which is given as

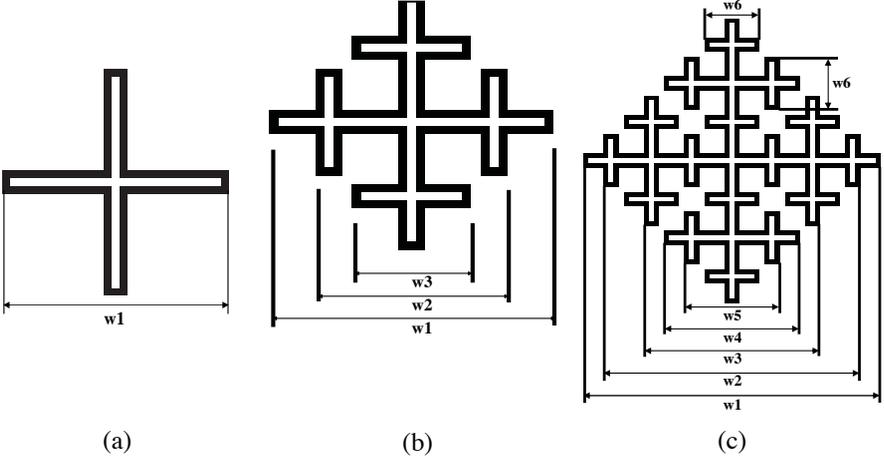

$$\begin{aligned} \alpha_p &= k_0 \sin \theta \cos \varphi + 2\pi p / T_x \\ \beta_q &= k_0 \sin \theta \sin \varphi + 2\pi q / T_y \end{aligned}$$

$k_0$  is the wave number in free space,  $\theta$ ,  $\varphi$  are elevation and azimuth angle of the incident wave, respectively. It is noted that in Eq. (3) a rectangular array alignment is supposed. The EFIE is solved by the Galerkin's moment method, while rooftop basis function is used to expand the electric current. After the electric current is solved, the scattering matrix is ready to know.

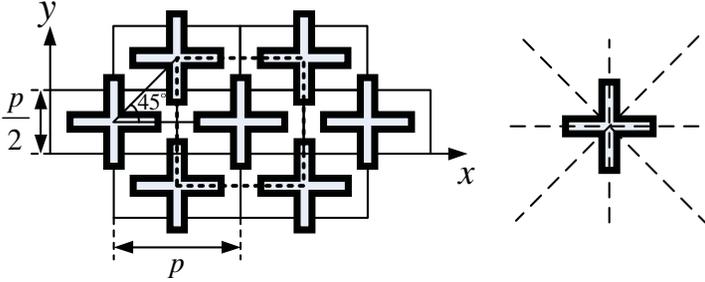

#### 4. NUMERICAL RESULTS

The fractal four legged elements of different orders are shown in Fig. 1. The black part means the aperture area. In order to make the elements more compact, as shown in Fig. 2, the array is aligned in a isosceles triangle way. It is noted that the isosceles triangle array can be seen as a rectangular array if two elements along  $y$ -axis are united as one element (see Fig. 2). Note that the elements are with eightfold symmetry. The FSS elements are all etched on a dielectric substrate, and Rogers RT5880 with thickness 1.27 mm is used as the substrate. The widths of the aperture line and the line enclosed by aperture line, denoted as  $w$ , are all the same for each element. The parameters of the FSS elements are given in Table 1. All dimensions are in millimeter. As that in [9], the ratio  $\sqrt{2}\lambda_1/p$  is used as a figure of merit, where  $\lambda_1$  is the first resonant wavelength. For all the three cases,  $\lambda_1$  is approximately equal to 150 mm. The coefficient  $\sqrt{2}$  is due to the fact that two elements are included in a unit cell. In order to avoid grating lobes, for normal incidence, the cutoff wavelength is given as [5]

$$\lambda_c = p / \sqrt{2}. \quad (4)$$

**Figure 1.** Fractal four-legged elements of different orders: (a) first order, (b) second order, (c) third order.

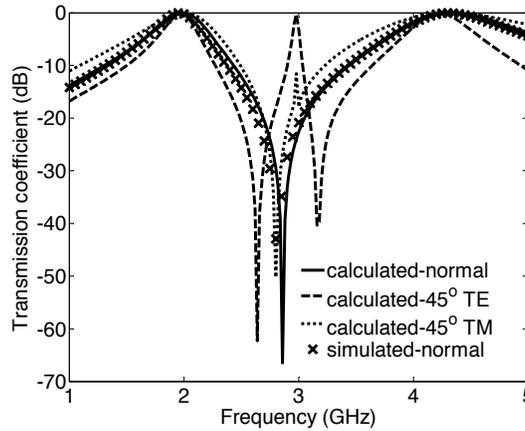

**Figure 2.** Schematic of array alignment and the symmetry property of elements.

While for  $45^\circ$  incidence, the cutoff wavelength is given as

$$\lambda_c = p/\sqrt{2} * (1 + \sin(45^\circ)). \quad (5)$$

Therefore, the cutoff frequencies for the three cases are 5.47 GHz, 8.83 GHz, and 12.14 GHz, respectively.

Figure 3 shows the transmission coefficient of the FSS with the first order fractal four-legged elements. Both normal incidence and  $45^\circ$  incidence and both TE and TM polarization are considered. The simulated results by Ansoft HFSS are also given for comparison. The calculated results are in a good agreement with the simulated. It can be seen that the first resonance is almost the same for different incident

**Figure 3.** Transmission coefficient of the FSS with fractal first order four legged elements.

angles and polarizations. The ratio  $\sqrt{2}\lambda_1/p$  is

$$\sqrt{2}\lambda_1/p = \sqrt{2} * 150/45.44 = 4.67 \tag{6}$$

A second resonance is found at 4.34 GHz, 4.22 GHz, 4.32 GHz for normal incidence, 45° TE, and 45° TM, respectively. The shift of this resonant frequency is 0.12 GHz.

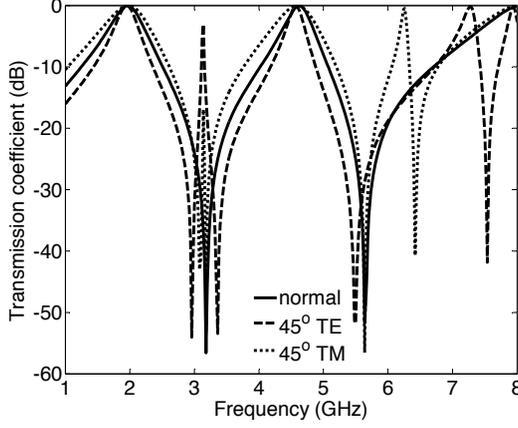

Figure 4 shows the transmission coefficient of the FSS with the second order fractal four legged elements. The first resonance is also stable for different incident angles and polarizations. The ratio  $\sqrt{2}\lambda_1/p$  is

$$\sqrt{2}\lambda_1/p = \sqrt{2} * 150/28.16 = 7.53 \tag{7}$$

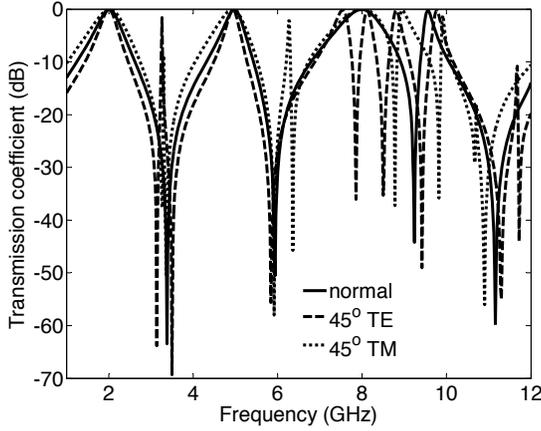

A second resonance is found at 4.62 GHz, 4.58 GHz, 4.60 GHz for normal incidence, 45° TE, and 45° TM, respectively. The shift of this resonant frequency is 0.04 GHz, much less than that of the first case.

**Table 1.** Parameters of the FSS elements.

order	$p$	w	w1	w2	w3	w4	w5	w6
1	45.44	0.71	41.89					
2	28.16	0.44	25.96	15.40	11.88			
3	20.48	0.32	18.88	16.32	11.20	8.64	6.08	3.52

**Figure 4.** Transmission coefficient of the FSS with second order fractal four legged elements.

**Figure 5.** Transmission coefficient of the FSS with third order fractal four legged elements.

Figure 5 shows the transmission coefficient of the FSS with the third order fractal four legged elements. Again, the first resonance is stable for different incident angles and polarizations. The ratio  $\sqrt{2}\lambda_1/p$  is

$$\sqrt{2}\lambda_1/p = \sqrt{2} * 150/20.48 = 10.36 \quad (8)$$

A second resonance is found at 4.98 GHz, 4.94 GHz, 4.92 GHz for

normal incidence,  $45^\circ$  TE, and  $45^\circ$  TM, respectively. The shift of this resonant frequency is 0.06 GHz. Though there are two other resonances at 8.00 GHz and 9.56 GHz, they are not stable for different incident angles and polarizations.

## 5. CONCLUSIONS

FSSs with fractal four legged aperture elements of different orders are discussed. The results show that by using higher order fractal elements, small periodicity and multiband FSSs can be obtained. For the third order, the ratio  $\sqrt{2}\lambda_1/p$  reaches 10.36; four passbands for normal incidence are obtained, however, only the first two bands are stable for different incident angles and polarizations. Larger ratio and more bands for normal incidence are expected by using higher order fractal elements. In practice, the line width can not be infinite thin, but larger than a certain value due to the technologic reasons. This in turn restricts the fractal orders. It should be noted that the band ratio  $\lambda_2/\lambda_1$  can be tuned by changing the ratio  $w_4/w_1$ . The result is in a good agreement with that by Ansoft HFSS.
