Scattering Analysis of Buried Objects by Using FDTD with Nonuniform Meshes

Min Zhang, Cheng Liao[*]**, Xiang-Zheng Xiong, and Xiaomin Xu**

Abstract—This paper presents a finite-difference time-domain (FDTD) method of the infinite half-space with nonuniform meshes, aiming to speed up the FDTD calculation of scattering of buried objects. Two 1-D modified FDTD equations are employed to set plane wave excitation of the infinite half-space scattering problems. In order to reduce calculation time and meshes, a method with nonuniform meshes is applied. Fine grids are used for the buried objects and underground while coarse grids are applied for other regions. The 1-D modified FDTD equations with nonuniform meshes are derived, and the settings of total-field/scattering-field (TF-SF) boundary are given. Finally, the proposed method is applied to calculate the transient scattering field of a buried mine. Numerical results demonstrate the validity of the method, and the simulation time is significantly reduced compared to uniform meshes FDTD.

1. INTRODUCTION

The FDTD method has been successfully used to solve many kinds of scattering problems [1–4], such as the stealth and anti-stealth of aircraft [5, 6] and detecting or imaging of unknown targets [7–9]. It is convenient to implement the FDTD scheme for the scattering of objects in free space. The incident plane wave can be easily set according to the equivalence principle. However, the FDTD TF-SF boundary is much more complex in half-space, especially in layered medium. In order to solve these problems, Wong et al. introduced the three-wave method [10], which needs to calculate the reflection and transmission waves on the interface in advance. It will be more difficult when the infinite half-space becomes layered medium. Winton et al. derived the 1-D modified FDTD equations to simulate plane wave incident to layered media in 2D scheme (TM-wave and TE-wave) [11]. Based on [11], Jiang et al. proposed a Π-shaped TF-SF boundary [12]. By carrying out different operations on each side of the TF-SF boundary, the plane wave can be injected in 3-D problems, even in layered and dispersive medium.

Although the difficulties of injecting the plane wave source for the infinite half-space FDTD has been overcome, many useful techniques of FDTD for free space have not been generalized for half-space geometries. One of them is the nonuniform meshes techniques. It can be found that the methods mentioned before were used in uniform grids. As we know, there are some areas which should frequently apply fine grids in FDTD calculation, such as the complex constructions of targets and underground soil with high dielectric constant. For uniform grids FDTD, coarse meshing leads to low accuracy, and fine meshing costs large amount of computing resources.

In this paper, the 1-D modified FDTD equations based on [11, 12] are derived in a nonuniform meshing scheme. Then the processing of incident plane wave for TF-SF boundary is given. Finally, the scattering fields of a buried mine are calculated, and the simulation time and number of meshes are both significantly reduced compared with uniform meshes FDTD method.
Figure 1. Setting of the TF-SF boundary.

2. THEORY OF THE METHOD

Due to limited memory of computers, the infinite half-space region cannot be directly truncated by absorbing boundary of FDTD method. To overcome the difficulty, a part of the region is selected, and it is surrounded by the absorbing boundary. For a scattering problem in the presence of layered medium, it is difficult to set the TF-SF boundary. The major problem is the prior calculation of incident wave. In order to solve the problem, the 1-D modified FDTD equations are given in [11].

Assume that the TMy and TEy waves propagate in xoz 2-D plane. The incident angle is θ with respect to the z axis, which can be seen in Fig. 1. Then the 1-D modified Maxwell's equations of TMy wave can be shown as follows.

$$\frac{\partial E_{y1D}}{\partial z} = \mu_0 \frac{\partial H_{x1D}}{\partial t} \tag{1}$$

$$\frac{1}{\cos^2\theta}\frac{\partial H_{x1D}}{\partial z} = \varepsilon\frac{\partial E_{y1D}}{\partial t} + \sigma E_{y1D} \tag{2}$$

The equations of TEy wave can be written as:

$$\frac{\partial H_{y1D}}{\partial z} = -\varepsilon\frac{\partial E_{x1D}}{\partial t} - \sigma E_{x1D} \tag{3}$$

$$\frac{1}{\cos^2\theta}\frac{\partial E_{x1D}}{\partial z} = -\mu_0\frac{\partial H_{y1D}}{\partial t} \tag{4}$$

Discretizing Equations (1) and (2) in nonuniform meshes, the 1-D modified FDTD equations with nonuniform scheme can be derived as:

$$H_{x1D}^{n+1/2}(k+1/2) = H_{x1D}^{n-1/2}(k+1/2) - \frac{\Delta t}{\mu(k)\Delta z_k}\left[E_{y1D}^n(k+1) - E_{y1D}^n(k)\right] \tag{5}$$

$$E_{y1D}^{n+1}(k) = \frac{2\overline{\varepsilon(k)} - \overline{\sigma(k)}\Delta t}{2\overline{\varepsilon(k)} + \overline{\sigma(k)}\Delta t}E_{y1D}^n(k) + \frac{2\Delta t}{\left(2\overline{\varepsilon(k)} + \overline{\sigma(k)}\Delta t\right)}\left[\frac{H_{x1D}^{n+1/2}(k+1/2) - H_{x1D}^{n+1/2}(k-1/2)}{\Delta h_k \cos^2\theta}\right] \tag{6}$$

where

$$\Delta h_k = \frac{\Delta z_k + \Delta z_{k+1}}{2} \tag{7}$$

$$\overline{\varepsilon(k)} = \frac{\Delta z_k \varepsilon(k) + \Delta z_{k+1}\varepsilon(k+1)}{\Delta z_k + \Delta z_{k+1}} \tag{8}$$

$$\overline{\sigma(k)} = \frac{\Delta z_k \sigma(k) + \Delta z_{k+1}\sigma(k+1)}{\Delta z_k + \Delta z_{k+1}} \tag{9}$$

**Figure 2.** 1-D FDTD scheme with non-uniform meshes.

where Δz_k is the space step of E_{y1D} and Δh_k the space step of H_{x1D}, which is shown in Fig. 2. $\overline{\varepsilon(k)}$ is the weighted mean of $\varepsilon(k)$ and $\varepsilon(k+1)$, and $\overline{\sigma(k)}$ is the weighted mean of $\sigma(k)$ and $\sigma(k+1)$.

The iterative equations of TEy wave can also be derived in the same way. The fields on TF-SF boundary can be given correctly by using the 1-D equations because these equations include the reflection and transmission of the ground.

The setting procedure of TF-SF boundary in 2-D FDTD is as follows: Taking $ABDC$ as the TF-SF boundary, which is shown in Fig. 1. First of all, the 1-D modified FDTD is performed once on AB and CD, respectively, where $S1$ and $S2$ represent the point sources of the two FDTD calculations. Then the electric fields on AB and CD boundaries can be obtained from the 1-D FDTD results. Because the incident waveform of AC boundary is the same as that of the corner A or C, the incident fields can be derived with a proper time delay of point A or C. The BD boundary may be treated in the same way as AC, which can be extended into the CPML. Assume $\Delta T_{AA'}$ as the time delay between point A and A'. Then $\Delta T_{AA'}$ may be described as in Eq. (10).

$$\Delta T_{AA'} = |AA'| \cdot \sin(\theta)/c_0 = \sum_{i=i_A}^{i_{A'}-1} \Delta x_i \cdot \sin(\theta)/c_0 \tag{10}$$

Δx_i is the space step in FDTD calculation, which varies with the location of grid. If the time delay is not integral multiple of time step Δt, the linear interpolation will be used. Distinguished from the uniform FDTD, the mesh size of nonuniform FDTD is variable. We can adjust the mesh size to make the most time delays be integral multiple of the time step, then the errors caused by linear interpolation will be reduced.

Taking TMy wave for example, the 1-D modified FDTD results can only provide Ey and Hx components of incident wave. However, Hz component is also needed for the setting of AB and CD boundaries. To obtain the Hz component, a differential calculation is applied. For AB boundary, the 1-D modified FDTD should be performed once on $i = i_A$ and $i = i_A - 1$, respectively, then the Hz on

Figure 3. Incident plane in 3-D FDTD scheme.

$i = i_A - 1/2$ may be obtained with the following differential equation.

$$H_{z,inc}^{n+1/2}(i_A - 1/2, k) = H_{z,inc}^{n-1/2}(i_A - 1/2, k) - \frac{\Delta t}{u_{i_{A-1}}\Delta x_{i_{A-1}}} \left[E_{y1D}^n(i_A, k) - E_{y1D}^n(i_A - 1, k) \right] \quad (11)$$

The Hz component on $i = i_C + 1/2$ should also be obtained in the same way.

The method of injecting incident plane wave source for 2-D FDTD scheme has been introduced as mentioned above. For a 3-D FDTD scheme, a method mentioned in [13] is adopted. Firstly, a major incident plane should be set, shown in Fig. 3. Secondly, perform the 2-D FDTD calculation in the incident plane with the above method. Then project the 3-D TF-SF boundary on the incident plane and calculate the incident source on TF-SF boundary by linear interpolation. Finally, process the 3-D FDTD calculation. It is worth mentioning that the mesh sizes of 2-D FDTD and 3-D FDTD can also be fine-tuned to reduce the errors caused by linear interpolation.

In order to perform the near- to far-field transformation, the equivalence principle can be used in terms of equivalent electric and magnetic currents on a transformation surface that surrounds the scatterer [14].

3. NUMERICAL RESULTS

Figure 4 shows a simple buried object that demonstrates the presented method. The dielectric cube has dimensions of $0.1\,m \times 0.1\,m \times 0.1\,m$, relative permittivity of 2.9, and conductivity of $0.00167\,S/m$. The center of the cube lies $0.1\,m$ beneath the surface of the ground. The relative permittivity and conductivity of the infinite ground are $\varepsilon_{r0} = 3.0$ and $\sigma_0 = 0.00334\,S/m$, respectively. The incident plane wave is Gaussian pulse with pulse width of $2\,ns$, and the amplitude of electric field is $1.0\,V/m$. In the simulation, the mesh sizes vary from $15\,mm$ to $25\,mm$.

Figures 5(a) and (b) show the scattered far field of the buried cube for TM wave incidence with $\theta = 0°$ and $\theta = 60°$, respectively. Figs. 6(a) and (b) show the corresponding results for TE wave incidence. It may be seen that all the results are in good agreements with Hill's results [15].

For TM wave incidence, it can be found that the amplitudes of scattered far fields with $\theta = 60°$ are bigger than that of $\theta = 0°$. However for TE wave incidence, the conclusion is on the contrary.

In order to evaluate the errors of the proposed method, the leakages of electric wave in SF region are tested. As the leakages will be merged with the scatter fields, the buried object in Fig. 4 is removed, and

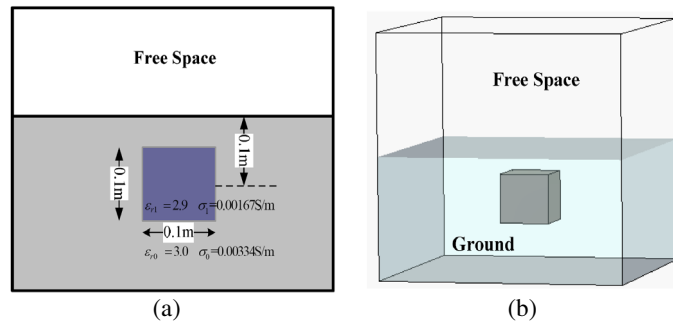

Figure 4. A dielectric cube buried in infinite ground: (a) section (b) 3D view.

Table 1. The leakages of non-uniform meshes FDTD and uniform meshes FDTD.

| Name	Non-uniform FDTD		Uniform FDTD	
	$\theta = 0°$	$\theta = 60°$	$\theta = 0°$	$\theta = 60°$
Leakages for TM incidence (V/m)	5.436E-4	2.436E-3	3.756E-4	1.561E-3
Leakages for TE incidence (V/m)	3.349E-4	1.562E-3	2.861E-4	1.033E-3

Figure 6. Scattered far fields for TE wave incidence at 0.6 GHz: (a) incident angle $\theta = 0°$, (b) incident angle $\theta = 60°$.

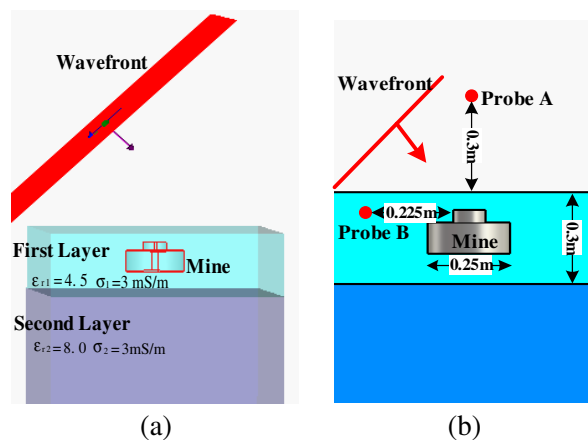

**Figure 7.** A dielectric cube buried in infinite ground: (a) elevation (b) section.

**Figure 8.** Waveform of Ey: (a) probe A, (b) probe B.

Figure 9. Electric fields of different time in xoz plane: (a) $t = 2.0$ ns, (b) $t = 4.0$ ns, (c) $t = 5.5$ ns, (d) $t = 7.0$ ns.

a plane wave injected to ground is simulated. Uniform meshes FDTD is also used for the simulation, and the mesh size is 15 mm. Table 1 shows the maximum leakages of electric wave for different incidences. Leakage of oblique incidence is lager than that of normal incidence. TM wave incidence produces more leakages than TE wave. The nonuniform differential scheme may increase errors, and it leads to more leakages than uniform meshes.

Then the method is applied to simulate the scattering of a buried mine. The plane wave is Gaussian pulse with y-polarized and incident angle $\theta = 0°$. The Gaussian pulse has width $W = 2$ ns and amplitude

Table 2. The mesh size and time needed by the two methods for the simulation of buried mine.

Name	Smallest Mesh	Largest Mesh	Meshes	Run Time
Non-uniform	10 mm	22 mm	0.408 million	47.2 sec
Uniform	10 mm	10 mm	1.152 million	128.9 sec

$A = 1\,\mathrm{V/m}$. It can be seen in Fig. 7 that the infinite ground has two layers with $\varepsilon_{r1} = 4.5\ \sigma_1 = 3\,\mathrm{mS/m}$ and $\varepsilon_{r2} = 8.0\ \sigma_2 = 3\,\mathrm{mS/m}$ for top and bottom, respectively. The dimensions of the mine are: diameter $R = 0.25\,\mathrm{m}$ and thickness $t = 0.1\,\mathrm{m}$.

The waveforms of electric field Ey in positions A and B are shown in Figs. 8(a) and (b), respectively. The results obtained from the proposed method are in good agreements with that of the uniform mesh FDTD. The size of meshes, number of meshes and time cost are shown in Table 2. In uniform FDTD simulation, the mesh sizes are 10 mm. But in nonuniform FDTD simulation, the mesh sizes vary from 10 mm to 22 mm. It costs only 47.2 seconds by using proposed method, meanwhile 128.7 seconds is needed for uniform mesh FDTD.

Figures 9(a), (b), (c) and (d) show the electric fields of different times in xoz plane, respectively. The reflected wave can be seen when plane wave reaches the interfaces. There are also obviously scattered fields around the mine.

4. CONCLUSIONS

This paper presents a novel method for fast calculation of the scattering fields of buried objects. By utilizing nonuniform mesh in a 1-D modified FDTD, the plane wave is injected successfully, and the computing resources can be saved significantly. A dielectric cube buried in infinite media is used to validate this method. The scattered far fields predicted by the method are in good agreements with Hill's. Moreover, the method is applied to the scattering calculation of a mine buried in layered medium, and significant reductions of calculation time and meshes are obtained.
